ABHA Number Update API - Functional Documentation

Purpose
This document describes the background, business problem, operational challenges, and the solution implemented through the ABHA Number Update API. The API was introduced to support claim processing for cyclic procedures in lower testing environments where biometric authentication is mandatory for every hospital visit.

Background

For cyclic procedures, beneficiary biometric authentication is mandatory during every hospital visit. During testing in lower environments, dummy beneficiaries are commonly used for validating end-to-end claim flows. However, biometric authentication can only be performed by a real individual, resulting in the generation of a token associated with a real ABHA number. Consequently, biometric records are stored against the real ABHA number while claim processing is performed using the dummy beneficiary data.

Problem Statement

Because biometric records are linked to the real ABHA number and the claim is raised using the dummy beneficiary ABHA number, the system is unable to locate the expected biometric records during claim validation. This mismatch causes claim processing failures.

Observed Error Message

No biometric records found for the beneficiary for %s. Please ensure correctness of admission date and discharge date for the day for cyclic procedure %s. Hence case will not be processed for case number (%s) with correlation id as (%s) at (%s).

To proceed with testing, database records had to be manually updated by replacing the real ABHA number captured during biometric authentication with the dummy ABHA number used in the claim request. This dependency on manual database intervention required technical support, introduced delays, increased testing effort, and slowed claim processing verification.

Solution

To eliminate repeated manual database updates, an API was developed to automatically replace the real ABHA number with the corresponding dummy ABHA number. This enables users and testers to perform the mapping themselves and ensures that claim validation can successfully locate biometric records associated with the dummy beneficiary used in testing.

Benefits

• Eliminates manual database updates.
• Reduces dependency on technical or support teams.
• Speeds up claim testing for cyclic procedures.
• Provides a self-service mechanism for users.
• Reduces turnaround time for claim validation and processing.

API Details

Endpoint:
https://apisbx.abdm.gov.in/pmjay/sbxhcx/participanthcxservice/update/abhanumber

Sample curl Request:

```
curl --location --request POST
'https://apisbx.abdm.gov.in/pmjay/sbxhcx/participanthcxservice/update/abhanumber'
--header 'Accept: application/json'
--header 'Content-Type: application/json'
--header 'bearer_auth: Bearer {{Auth}}'
--data-raw '{
   "realAbha":"12345678901234",
   "dummyAbha":"12345678904321"
}'
```

Conclusion

The ABHA Number Update API addresses a key testing challenge for cyclic procedure claim processing. By automatically replacing the real ABHA number generated through biometric authentication with the designated dummy ABHA number, the solution ensures smoother testing, reduces manual effort, and improves overall efficiency of claim validation workflows.
